Exception and Exception Handling

What is an exception?

An **exception** is a situation, which occurred by the runtime error. In other words, an exception is a runtime error. An exception may result in loss of data or an abnormal execution of program. Exception handling is a mechanism that allows you to take appropriate action to avoid runtime errors.

The default behavior for unexpected is to call **terminate**, and the default behavior for terminate is to call **abort()**, so the program is to halt. Local variables in active stack frames are not destroyed, because **abort()** shuts down program execution without performing such cleanup.

```
class Polygon
  protected:
    int width, height;
  public:
    Polygon (int a, int b) : width(a), height(b) {}
    virtual int area () = 0;
    void printarea()
      { cout << this->area() << '\n'; }
};
class Rectangle: public Polygon
  public:
    Rectangle(int a,int b) : Polygon(a,b) {}
    int area()
      { return width*height; }
void process()
  Polygon *p = new Rectangle(4,5);
  p->printarea();
                    If an exception occurs, the following
                    statements can not be executed.
  delete p;
                    The memory can not be free.
```

```
void process()
{
   Polygon *p = new Rectangle(4,5);
   try{
      p->printarea();
   }catch(...){
      delete p;
      throw;
   }
   delete p;
}
```

One solution is to use try-catch block to catch and handle the exception. In catch block, free the memory and throw the exception to the caller.

```
void process()
{
    shared_ptr<Polygon> sp(new Rectangle(10,20));
    sp->printarea();
}
```

Another solution is to use smart pointer, thus there is no need to free the memory.

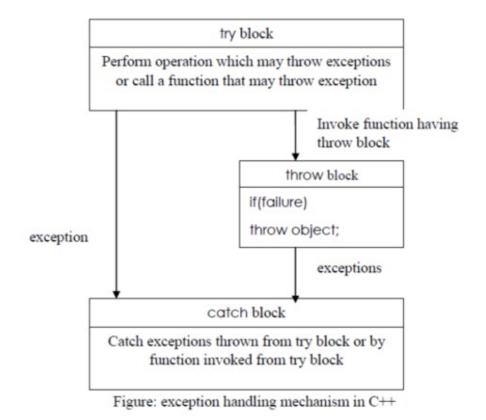

Using an object to store a resource that needs to be automatically released(resources should be encapsulated inside objects) and relying on that object's destructor to release it.

Exception handling

Exceptions provide a way to react to exceptional circumstances (like runtime errors) in programs by transferring control to special functions called *handlers*. C++ provides **three keywords** to support exception handling.

- try: The try block contain statements which may generate exceptions. When an exceptional circumstance arises within that block, an exception is thrown that transfers the control to the exception handler. If no exception is thrown, the code continues normally and all handlers are ignored.
- throw: When an exception occur in try block, it is thrown to the catch block using throw keyword.
- catch: The catch block defines the action to be taken when an exception occur. Exception handlers are declared with the keyword catch, which must be placed immediately after the try block.

Example of a program with exception handling using try and catch, throw an exception in try block in main()

```
exceptions > @ exceptiondemo1.cpp > ...
      #include <iostream>
      using namespace std;
      int main()
           int a, b;
          double d;
           a = 5;
           b = 0;
          try{
 11
 12
               if(b == 0)
                   throw the divisor can not be zero!";
 13
               d = (double)a/b;
              cout << "The quotient of " << c '' '' << b << " is:" << d << endl;</pre>
           }catch(sonst char* perror){
 17
               count << perror << endl;
           }catch(int code){
               cout << "Exception code:" << code << endl;</pre>
 21
 22
           return 0;
```

The divisor can not be zero!

Example of a program with exception handling using try and catch, throw an exception in other function, handlers are in main()

```
exceptions > 😉 exceptiondemo2.cpp > ...
      #include <iostream>
      using namespace std;
      double Quotient(int a, int b);
      int main()
          int a, b;
          double d;
          a = 5;
          b = 0;
          try{
              d = Quotient(a,b);
              cout << "The quotient of " << a << "/" << b << " is:" << d << endl;
          }catch(const char* perror){
              count << perror << endl;
          }catch(int code){
              cout  "Exception code:" << code << endl;</pre>
          return 0;
                      match
      double Quotient(int a, int b)
          if(b == 0)
              throw (404;
          return (double)a/b;
```

Exception code:404

Note: In general, no conversions are applied when matching exceptions to catch clauses.

```
exceptions > 😉 exceptiondemo2.cpp > ...
     #include <iostream>
      using namespace std;
     double Quotient(int a, int b);
     int main()
          int a, b;
          double d;
          a = 5;
 10
          b = 0;
11
          try{
13
              d = Quotient(a,b);
              cout << "The quotient of " << a << "/" << b << " is:" << d << endl;</pre>
          }catch(const char* perror){
              cout << perror << endl;</pre>
          }catch(double code){
              cout  "Exception code:" << code << endl;</pre>
          return 0;
                       does not
                       match
      double Quotient(int a, int b)
          if(b == 0)
              throw (404;)
          return (double)a/b;
```

terminate called after throwing an instance of 'int'
Aborted

```
exceptions > 🚭 exceptiondemo3.cpp > .
                                                                                         Define and using exception class
     #include <iostream>
     #include <limits>
     using namespace std;
     class RangeError{
     private:
                                                     Define your exception class
         int iVal;
         RangeError(int _iVal) {iVal = _iVal;}
         int getVal() {return iVal;}
     char to_char(int n)
              < nemeric_limits<char>::min() || n > numeric_limits<char>::max())
            torow RangeError(n);
                                        Throw the exception and
         return (char)n;
                                          invoke the constructor
     void gain(int n)
         try{
                                                                  Catch and handle the exception
            char c = to char(n);
            cout << n << " is character " << c << endl;</pre>
        }catch(RangeError &re){
            cerr << "Cannot convert " << re.getVal() << " to char\n" << endl;</pre>
            cerr << "Range is " << (int)numeric_limits<char>::min();
            cerr << " to " << (int)numeric limits<char>::max() << endl;</pre>
                                                                                                                   Cannot convert -130 to char
     int main()
                                                                                                                   Range is -128 to 127
        gain(-130);
        return 0;
```

```
exceptions > @ exceptiondemo4.cpp > ...
      #include <iostream>
      using namespace std;
      class MathException { };
      class OverflowException : public MathException{ };
      class UnderflowException : public MathException{ };
      class ZeroDivideException : public MathException { };
      double divide(int numerator, int denominator)
           if(denominator == 0)
 11
               throw ZeroDivideException();
 12
 13
           double d = (double) numerator/denominator;
 15
           return d;
 17
       int main()
           try{
               cout << divide(6,0) << endl;</pre>
 21
           }catch(ZeroDivideException& zd){
               cerr << "Zero Divide Error" << endl;
 23
           }catch(OverflowException& oe){
               cerr << "Overflow Error" << endl;</pre>
           }catch(UnderflowException& ue){
               cerr << "Underflow Error" << endl;</pre>
           }catch(MathException& me){
               cerr << "Math Error" << endl;</pre>
           return 0;
```

Handling exceptions from an inheritance hierarchy

Note: A kind of conversion is applied when matching exceptions to **catch clauses**. That is inheritance-based conversions. A catch clause for base class exceptions is allowed to handle exceptions of derived class types, too.

Zero Divide Error

```
SOUTHERN UMITALIAN SOUTHERN UMIT
```

```
exceptions > G exceptiondemo4.cpp > ...
      #include <iostream>
      using namespace std;
      class MathException { };
      class OverflowException : public MathException{ };
      class UnderflowException : public MathException{ };
      class ZeroDivideException : public MathException { };
      double divide(int numerator, int denominator)
 10
 11
          if(denominator == 0)
 12
               throw ZeroDivideException()
                       double) numerator/denominator;
 15
           return d;
 17
      int main()
           try{
               cout << divide(6,0) << endl;</pre>
 21
           }catch(MathException& me){
               cerr << "Math Error" << endl;</pre>
           }catch(ZeroDivideException& zd){
               cerr << "Zero Divide Error" << endl;</pre>
           }catch(OverflowException& oe){
               cerr << "Overflow Error" << endl;</pre>
           }catch(UnderflowException& ue){
               cerr << "Underflow Error" << endl;</pre>
           return 0;
```

Note: catch clauses are always tried in the order of their appearance. Hence, it is possible for an exception of a derived class type to be handled by a catch clause for one of its base class types.

Compilers may warn you if a catch clause for a derived class comes after one for a base class.

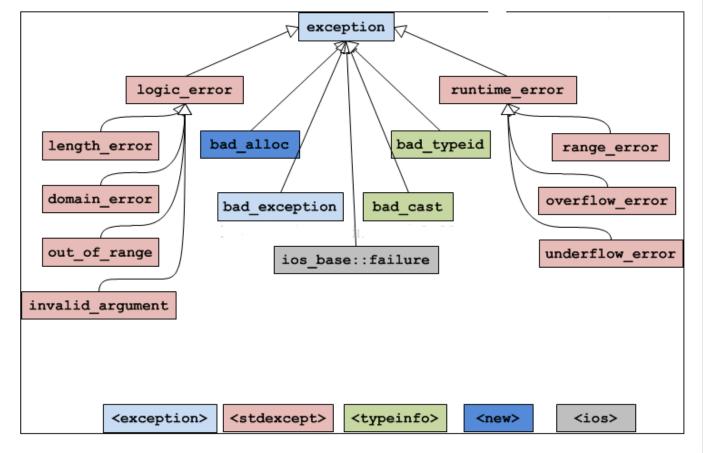

C++ Standard Exceptions

C++ provides a list of standard exceptions defined in which we can use in our

programs.

Exception	Description		
std::exception	An exception and parent class of all the standard C++ exceptions.		
std::bad_alloc	This can be thrown by new .		
std::bad_cast	This can be thrown by dynamic_cast .		
std::bad_exception	This is useful device to handle unexpected exceptions in a C++ program		
std::bad_typeid	This can be thrown by typeid.		
std::logic_error	An exception that theoretically can be detected by reading the code.		
std::domain_error	This is an exception thrown when a mathematically invalid domain is used		
std::invalid_argument	This is thrown due to invalid arguments.		
std::length_error	This is thrown when a too big std::string is created		
std::out_of_range	This can be thrown by the at method from for example a std::vector and std::bitset<>::operator.		
std::runtime_error	An exception that theoretically can not be detected by reading the code.		
std::overflow_error	This is thrown if a mathematical overflow occurs.		
std::range_error	This is occured when you try to store a value which is out of range.		
std::underflow_error	This is thrown if a mathematical underflow occurs.		

noexcept, noexcept(true), and throw() are equivalent.

Syntax

noexcept	(1)	
noexcept(expression)	(2)	
throw()	(3)	(deprecated in C++17) (removed in C++20)

```
Exception specification used in function declaration, with no argument
   indicates that the function is not allowed to throw any exceptions.

   exception () throw(); //constructor
   exception (const exception&) throw(); //copy constructor
   exception& operator= (const exception&) throw(); //assignment operator
   virtual ~exception() throw(); //destructor
   virtual const char* what() const throw(); //virtual function
}
```

what() is a public method provided by **exception class** which returns a string and it has been overridden by all the child exception classes.

Define your own exception class derived from exception class and override what() method

```
exceptions > G exceptiondemo5.cpp > ...
       #include <iostream>
       using namespace std;
       class MyException : public exception
       public:
           const char* what() const throw()
               return "C++ Exception.";
 11
       };
 12
       int main()
 15
           try{
               throw MyException();
           }catch(MyException& me){
 17
               cout << "MyException is caught." << endl;</pre>
               cout << me.what() << endl;</pre>
           }catch(exception& e){
                cout << "Base class exception is coutch." << endl;</pre>
 22
               cout << e.what() << endl;</pre>
 23
           return 0;
```

MyException is caught.
C++ Exception.

Note: use catch-by-reference for exception objects

catch-by-value:Derived class exception objects caught as base class exceptions have their derivedness "sliced off." Such "sliced" objects are base class objects: they lack derived class data members, and when virtual functions are called on them, they resolve to virtual functions of the base class. So use **catch-by-reference** for exception objects and invoke the virtual function of the derived class.

```
exceptions > @ exceptiondemo6.cpp > ...
      #include <iostream>
      using namespace std;
      class MyException : public exception
                                                                  It will not throw any exception
      public:
          virtual const char* what() const(noexcept)
              return "C++ Exception.";
 10
 11
                                                                         Base class exception is cautch.
      int main()
 13
                                                                          std::exception
                                     Catch the exception
          try{
                                                                       Invoke what() of the exception class
              throw MyException();
                                     by value
          }catch(exception e)
 17
                                                                       rather than the MyException class.
              cout << "Base class exception is cautch." << endl;
              cerr << e.what() << endl;</pre>
 21
          return 0;
```

```
exceptions > @ exceptiondemo6.cpp > ...
      #include <iostream>
      using namespace std;
                                                                 It is overriding a virtual method of the base class.
      class MyException : public exception
      public:
          virtual const char* what() const noexcept (override
              return "C++ Exception.";
 11
      };
 12
      int main()
                                      Catch the exception
 15
          try{
                                      by reference
              throw MyException();
          }catch(exception& e){
 17
              cout << "Base class exception is cautch." << endl;</pre>
                                                                             Base class exception is cautch.
              cerr << e.what() << endl;</pre>
                                                                             C++ Exception.
 21
          return 0;
 22
                                                                            Invoke what() of the MyException class
                                                                            not the exception class.
```

Assertions in C/C++

Assertions are statements used to test assumptions made by programmers. It is designed as a macro in C/C++. Following is the syntax for assertion:

void assert(int expression);

If the expression evaluates to 0 (false), then the expression, source code filename, and line number are sent to the standard error, and then **abort()** function is called.

```
noexceptions > G testassert.cpp > ...

1  #include <assert.h>
2  #include <iostream>
3  using namespace std;

4
5  int main()
6  {
7     int x = 7;
8     //x is accidentally changed to 9 */
9     x = 9;
10
11     // Programmer assumes x to be 7 in rest of the code
12     assert(x == 7);
13
14     // Rest of the code
15     cout << "The original value of x is 7" << endl;
16
17     return 0;
18 }</pre>
```

```
source code filename and line number

a.out: testassert.cpp:12: int main(): Assertion x == 7' failed.

Aborted

abort() function is called and display message on the screen.
```

Assertions are mainly used to check logically impossible situations. For example, they can be used to check the state of a code which is expected before it starts running, or the state after it finishes running.

Verify the validity of the passed argument at the beginning of the function.

```
int resetBufferSize(int nNewSize)
{
    assert(nNewSize >= 0);
    assert(nNewSize <= MAX_BUFFER_SIZE);
    ...
}</pre>
```

```
// is not recommended
assert(nOffset>=0 && nOffset+nSize<=m_nInfomationSize);

// is recommended, each assert test only on condition
assert(nOffset >= 0);
assert(nOffset+nSize <= m_nInfomationSize);</pre>
```

- Each assert tests only one condition, because when multiple conditions are tested at the same time,
 it is not intuitive to determine which condition failed if the assertion failed.
- Ignores assertions. We can completely remove assertions at compile time using the preprocessor NDEBUG. Put #define NDEBUG at the beginning of the code, before inclusion of <assert.h>.
 Therefore, this macro is designed to capture programming errors, not user or run-time errors, since it is generally disabled after a program exits its debugging phase.

Exercise:

1. Are there any warnings in the program below when it is complied? What the warnings mean? Run the program regardless of warnings and explain the result to SA. Fix the warnings and run the program again.

```
#include <iostream>
#include <string>
using namespace std;
class MyException: public exception
public:
  MyException(const string& msg): m msg(msg)
    cout << "MyException::MyException - set m msg to:" << m msg << endl;</pre>
  ~MyException()
    cout << "MyException::~MyException" << endl;</pre>
 virtual const char* what() const throw ()
    cout << "MyException::what" << endl;</pre>
    return m_msg.c_str();
 const string m_msg;
void throwDerivedException()
  cout << "throwDerivedException - thrown a derived exception" << endl;</pre>
  string execptionMessage("MyException thrown");
  throw (MyException(execptionMessage));
```

```
void illustrateDerivedExceptionCatch()
  cout << "illustrateDerivedExceptionsCatch - start" << endl;</pre>
  try
     throwDerivedException();
  catch (const exception& e)
    cout << "illustrateDerivedExceptionsCatch - caught an std::exception, e.what:" << e.what() << endl;</pre>
    // some additional code due to the fact that std::exception was thrown...
  catch(const MyException& e)
    cout << "illustrateDerivedExceptionsCatch - caught an MyException, e.what::" << e.what() << endl;
    // some additional code due to the fact that MyException was thrown...
  cout << "illustrateDerivedExceptionsCatch - end" << endl;</pre>
int main(int argc, char** argv)
  cout << "main - start" << endl:
  illustrateDerivedExceptionCatch();
  cout << "main - end" << endl;
  return 0:
```

2. Write a function **calculateAverage()** which takes four int arguments, which are marks of four courses, and returns their average as a float number.

The **calculateAverage()** function should take only valid range for marks which is between 0-100. If the marks are out of range throw an **OutOfRangeException** – define this exception as a class.

Invoke the calculateAverage() function in main function and get the following inputs and outputs:

Please enter marks for 4 courses:70 80 90 67
The average of the four courses is 76.75
Would you want to enter another marks for 4 courses(y/n)?y
Please enter marks for 4 courses:120 56 89 99
The parameter 1 is 120 which out of range(0-100).
Would you want to enter another marks for 4 courses(y/n)?y
Please enter marks for 4 courses:90 -87 67 92
The parameter 2 is -87 which out of range(0-100).
Would you want to enter another marks for 4 courses(y/n)?n
Bye, see you next time.
